Sandoz Ofloxacin (Ofloxacin Ophthalmic Solution USP, 0.3%)

THERAPEUTIC CLASSIFICATION

Antibacterial Agent

ACTION AND CLINICAL PHARMACOLOGY

The primary mechanism of action of ofloxacin appears to be the specific inhibition of DNA gyrase (topoisomerase II). This enzyme is responsible for the negative supercoiling of bacterial DNA and consequently for its topological configuration, governing functions such as RNA transcription, protein synthesis, DNA replication and repair functions.

INDICATIONS AND CLINICAL USE

Sandoz Ofloxacin (Ofloxacin Ophthalmic Solution USP, 0.3%) is indicated for the treatment of conjunctivitis when caused by susceptible strains of the following bacteria:

**Gram Positive Bacteria**
- *Staphylococcus aureus*
- *Staphylococcus epidermidis*
- *Streptococcus pneumoniae*

**Gram Negative Bacteria**
- *Haemophilus influenzae*

To reduce the development of drug-resistant bacteria and maintain the effectiveness of Ofloxacin Ophthalmic Solution 0.3% and other antibacterial drugs, Ofloxacin Ophthalmic Solution 0.3% should be used only to treat infections that are proven or strongly suspected to be caused by bacteria.

CONTRAINDICATIONS

Ofloxacin Ophthalmic Solution 0.3% is contraindicated in patients with a history of hypersensitivity to ofloxacin or to any of the components of this medication. A history of hypersensitivity to other quinolones also contraindicates use of ofloxacin.

WARNING
Ofloxacin Ophthalmic Solution 0.3% is not for injection into the eye.

In patients receiving systemic quinolone therapy, serious and occasionally fatal hypersensitivity (anaphylactic) reactions, some following the first dose, have been reported. Some reactions were accompanied by cardiovascular collapse, loss of consciousness, tingling, angioedema (including laryngeal, pharyngeal or facial edema), airway obstruction, dyspnea, urticaria, and itching. Only a few patients had a history of hypersensitivity reactions. Serious anaphylactic reactions may require immediate emergency treatment with epinephrine. Oxygen, intravenous steroids and airway management, including intubation, should be administered as clinically indicated.

Stevens-Johnson syndrome has been reported in patients receiving topical ophthalmic ofloxacin; however, a causal relationship has not been established.

Hypersensitivity reactions including angioedema, dyspnea, anaphylactic reaction/shock, oropharyngeal swelling, and tongue swollen have been reported with Ofloxacin Ophthalmic Solution 0.3% (see Post-Market Adverse Drug Reactions, Immune System Disorders). If an allergic reaction to ofloxacin occurs, discontinue the drug. Use Sandoz Ofloxacin with caution in patients who have exhibited sensitivities to other quinolone antibacterial agents.

**Susceptibility/Resistance**

*Development of Drug Resistant Bacteria*

Prescribing Ofloxacin Ophthalmic Solution 0.3% in the absence of a proven or strongly suspected bacterial infection is unlikely to provide benefit to the patient and risks the development of resistant organisms.

*Potential for Microbial Overgrowth*

Prolonged use of Ofloxacin Ophthalmic Solution 0.3% may result in overgrowth of nonsusceptible organisms, including fungi. Whenever clinical judgement dictates, the patient should be examined with the aid of magnification, such as slit lamp biomicroscopy and, where appropriate, fluorescein staining. If the infection is not improved within 7 days, cultures should be obtained to guide further treatment. If such infections occur, discontinue use and institute alternative therapy.

**PRECAUTIONS**

**General**

The systemic administration of quinolones has led to lesions or erosions of the cartilage in weight-bearing joints and other signs of arthropathy in immature animals of various species. Ofloxacin, administered systemically at 10 mg/kg/day in young dogs (equivalent to 150 times the maximum recommended daily adult ophthalmic dose), has been associated with these types of effects.

Corneal precipitates, and corneal perforation in patients with pre-existing corneal epithelial defect/corneal ulcer, have been reported during treatment with topical ophthalmic ofloxacin. However, a causal relationship has not been established.
The preservative in Sandoz Ofloxacin, benzalkonium chloride, may be absorbed by and cause discoloration of soft contact lenses. Sandoz Ofloxacin should not be administered while wearing soft contact lenses.

Patients should be instructed to avoid allowing the tip of the dispensing container to contact the eye or surrounding structures to avoid eye injury and contamination of eye drops.

As with any ocular medication, if transient blurred vision occurs at instillation, the patient should wait until the vision clears before driving or using machinery.

**Pregnancy:** There have been no adequate and well-controlled studies performed in pregnant women. Since systemic quinolones have been shown to cause arthropathy in immature animals, Ofloxacin Ophthalmic Solution 0.3% should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus.

**Nursing Mothers:** Because ofloxacin taken systemically is excreted in breast milk, and there is potential for harm to nursing infants, a decision should be made whether to temporarily discontinue nursing during therapy or not to administer the drug, taking into account the importance of the drug to the mother.

**Pediatric Use:** Safety and effectiveness of Ofloxacin Ophthalmic Solution 0.3% in children have not been established.

**Geriatric Use:** No comparative data are available with topical ofloxacin therapy in this age category versus other age groups.

**Drug Interactions**
Specific drug interaction studies have not been conducted with Ofloxacin Ophthalmic Solution 0.3%. Interactions between ofloxacin and caffeine have not been detected. Systemic use of ofloxacin with non-steroidal anti-inflammatory drugs has shown that the risk of CNS stimulation and convulsive seizures may increase. A pharmacokinetic study in 15 healthy males has shown that the steady-state peak theophylline concentration increased by an average of approximately 9% and the AUC increased by an average of approximately 13% when oral ofloxacin and theophylline were administered concurrently.

**ADVERSE REACTIONS**

**General**
Since a small amount of ofloxacin is systemically absorbed after topical administration, adverse events reported with systemic use could possibly occur.

**Ophthalmic Use of Ofloxacin**
The most frequently reported drug-related adverse reaction was transient ocular burning or
discomfort. Other reported reactions were ocular irritation, redness, stinging, itching, photophobia, tearing and dryness. One report of dizziness, one report of headache and one spontaneous report of toxic epidermal necrolysis have also been received.

**Systemic Effects of Ofloxacin**
As with all topical ophthalmic drugs, the potential exists for systemic effects. Ofloxacin used systemically has rarely been associated with serious side effects. Serious reactions reported for systemic dosing of ofloxacin include convulsions and increased intracranial pressure. For the oral dosage form of ofloxacin, gastrointestinal symptoms, mainly nausea/vomiting, pain/discomfort, diarrhea and anorexia, were reported most frequently, followed by central nervous system events (such as dizziness and headaches) and dermatological or hypersensitivity reactions. Additional effects seen with systemic dosing of ofloxacin and other fluoroquinolones are QT prolongation, exacerbation of myasthenia gravis symptoms, tendinitis and tendon rupture. Photophobia was reported rarely in clinical trials with systemic ofloxacin and phototoxicity has been reported with other drugs in this class.

**Post-Market Adverse Drug Reactions:**
The following adverse reactions have been identified during postmarketing use of Ofloxacin Ophthalmic Solution 0.3% in clinical practice. Because they are reported voluntarily from a population of unknown size, estimates of frequency cannot be made.

**Eye Disorders:**
Conjunctivitis, dry eye, eye edema, eye pain, foreign body sensation in eyes, hypersensitivity (including eye pruritus, eyelids pruritus), keratitis, lacrimation increased, ocular hyperemia, photophobia, vision blurred.

**Gastrointestinal Disorders:**
Nausea

**General Disorders and Administrative Site Conditions:**
Facial edema

**Immune System Disorders:**
Hypersensitivity (including angioedema, dyspnea, anaphylactic reaction/shock, oropharyngeal swelling and tongue swollen).

**Nervous System Disorders:**
Dizziness

**Skin and Subcutaneous Tissue Disorders:**
Periorbital edema

**SYMPTOMS AND TREATMENT OF OVERDOSAGE**
In the event of accidental ingestion of 10 mL of Ofloxacin Ophthalmic Solution, 0.3%, only 30 mg of ofloxacin would be ingested. Although this amount may not be clinically significant in terms of overdosage, there could be an increased potential for systemic reactions.

A topical overdosage of Ofloxacin Ophthalmic Solution is considered a remote possibility. Discontinue medication if heavy or protracted use is suspected. In the event of a topical overdose, flush the eye with a topical ocular irrigant.

For management of a suspected drug overdose, contact your regional Poison Control Centre.

**DOSAGE AND ADMINISTRATION**

One to two drops every two to four hours for the first two days, and then four times daily in the affected eye(s) for 8 days.

If superinfection occurs or if clinical improvement is not noted within 7 days, discontinue use and institute appropriate therapy.

Patients should be instructed to avoid allowing the tip of the dispensing container to contact the eye or surrounding structures to avoid eye injury and contamination of eye drops.

The preservative in Sandoz Ofloxacin, benzalkonium chloride, may be absorbed by and cause discoloration of soft contact lenses. Sandoz Ofloxacin should not be administered while wearing soft contact lenses.

**STORAGE AND STABILITY**

Sandoz Ofloxacin (Ofloxacin Ophthalmic Solution USP, 0.3%) is sterile in the unopened package. Store at 4°C to 30°C.

**DOSAGE FORMS, COMPOSITION AND PACKAGING**

Sandoz Ofloxacin (Ofloxacin Ophthalmic Solution USP, 0.3%) contains 0.3% ofloxacin with the following non-medicinal ingredients: benzalkonium chloride 0.005% (as preservative); sodium chloride; hydrochloric acid and/or sodium hydroxide to adjust pH; and purified water.

Sandoz Ofloxacin (Ofloxacin Ophthalmic Solution USP, 0.3%) is available for topical ophthalmic administration as a 0.3% sterile solution, and is supplied in plastic Drop-Tainer® bottles containing 5 mL.
PHARMACEUTICAL INFORMATION

Drug Substance

Common Name: Ofloxacin (INN, USAN, BAN)

Chemical Name: (±)-9-Fluoro-2,3-dihydro-3-methyl-10-(4-methyl-1-piperazinyl)-7-oxo-7H-pyrido[1,2,3-de]-1,4-benzoxazine-6-carboxylic acid
CAS-82419-36-1

Structural formula:

![Structural formula image]

Molecular Weight: 361.37 g/mol
Molecular Formula: C_{18}H_{20}F_{N3}O_{4}
Melting Point: 260-270°C (with decomposition)
Appearance: Cream to pale yellow crystalline powder
Solubility: Soluble in glacial acetic acid, sparingly soluble in chloroform, slightly soluble in water, methanol, ethanol or acetone
MICROBIOLOGY

Ofloxacin has *in vitro* activity against both gram-positive and gram-negative organisms. The primary mechanism of action of ofloxacin appears to be the specific inhibition of DNA gyrase (topoisomerase II). This enzyme is responsible for the negative supercoiling of bacterial DNA and consequently for its topological configuration, governing functions such as RNA transcription, protein synthesis, DNA replication and repair functions.

In a four-site study using a modified tube-dilution procedure, the *in vitro* activity of ofloxacin was evaluated against 419 ocular bacterial isolates of 55 species, in media supplemented with Ca++ and Mg++. Table 1 includes MIC values for five major ocular pathogens.

*In Vitro* Study of Ocular Isolates from Japanese Clinical Studies

An *in vitro* evaluation of the activity (MIC) of ofloxacin was conducted using a broth dilution technique, with 2,678 organisms cultured from the infected eyes of subjects enrolled in three clinical trials conducted in the clinics of public hospitals in Japan. The minimum concentrations necessary to inhibit 90% of the strains (MIC<sub>90</sub>) was 3.13 mcg/mL or less for all species tested except various *Pseudomonas species* and for *Streptococcus sanguis* isolates. MIC<sub>90</sub> values for ocular isolates are listed in Table 2.

Ofloxacin is bactericidal (3 log reduction in 1-2 hours) at 1 to 4 times the MIC.

**Bacterial Resistance:** The development of resistance to ofloxacin appears to be related to modification of bacterial DNA gyrase or to permeability changes in the bacterial outer cell.
membrane. Resistance to ofloxacin in vitro usually develops slowly (multiple-step mutation). Plasmid-mediated resistance or enzymatic inactivation have not been reported. Cross resistance among the fluoroquinolones has been observed, but development of clinically significant cross resistance to nonquinolone drugs appears to be uncommon.

**PHARMACOLOGY**

**ANIMAL PHARMACOLOGY**

**Pharmacodynamics**
The general pharmacological activities of ofloxacin have been studied in several mammalian species. At the maximum therapeutic dose levels, no effects on the central nervous system, cardiovascular and respiratory system, autonomic response or smooth and skeletal muscle were observed. These results are consistent with the infrequent occurrence of serious adverse effects with systemic clinical use of ofloxacin. Any pharmacological effects observed were frequently associated with doses at least 1000 times the anticipated maximal daily ocular dose.

**Systemic Metabolism and Pharmacokinetics**
The pharmacokinetics of ofloxacin have been studied in rats, dogs and monkeys. After oral administration, ofloxacin is well absorbed systemically and well distributed to all parts of the body. It is not extensively bound in the sera of the species tested. As with other quinolones, ofloxacin is found concentrated in melanocyte-containing tissues. Its binding to melanin is reversible. The ofloxacin-melanin binding phenomenon did not produce any observable adverse effects in eyes in a 6-month topical study in monkeys and in chronic oral toxicological studies. The drug wash-out from iris/ciliary body and choroid/retina of pigmented rabbits is rapid. Ofloxacin is also detected in the bone cartilage of both immature and adult dogs.

Ofloxacin passes through the placenta and into milk.

The serum elimination half-life of ofloxacin ranges from 5 to 7.5 hours following oral administration. More than 90% of the drug is excreted unchanged in the urine. Ofloxacin does not exert enzyme induction effects on hepatic microsomal enzymes and has little effect on hepatic enzyme inhibition.

**Ocular Pharmacokinetics**

**Animal**

After ophthalmic instillation as an eyedrop, ofloxacin is absorbed and distributed to all parts of the eye globe. 0.3% ofloxacin, applied topically to rabbit eyes five times at 5 minute intervals yielded concentrations of 5.6 mcg/mL in the bulbar conjunctiva, 5.1 mcg/mL in extraocular muscle, 6.5 mcg/mL in the cornea, 2.5 mcg/mL in the sclera, 1.5 mcg/mL in the aqueous humor, 1.0 mcg/mL in the iris and ciliary body, 0.05 mcg/mL in the vitreous body, a trace in the lens, retina and choroid, and no detectable ofloxacin in the serum one hour after instillation.

Single dose topical administration in rabbit eyes produced average tear concentrations beginning
at 2207 mcg/g and declining to 34 mcg/g 20 minutes post-dosing. The tear concentration was 2.5 mcg/g 6 hours post-dosing.

**Human**
Administering 0.3% ofloxacin topically 4 times daily to the eyes of 30 normal healthy adults resulted in tear ofloxacin concentrations ranging from 1.2 to 22 mcg/g (mean 9.2 mcg/g) four hours after the first dose on the eleventh day of treatment. The mean tear concentration varied between 5.7 and 31 mcg/g during the time period between 5 and 40 minutes after instillation of the second dose on day 11.

In this same study, mean serum plateau levels of 0.97 ng/mL after the first dose (day 1) and 1.66 ng/mL after the 41st dose (day 11) were achieved. The maximum serum level from multiple topical dosing (1.9 ng/mL) was approximately 2000-fold less than the maximum serum level achieved from treatment with a single 300 mg oral dose (4620 ng/mL).

Time to reach 90% of the plateau serum concentration was 0.9 hours after the initial dose on Day 1 compared with 0.5 hours on Day 11, indicating a change in the rate of systemic absorption from ophthalmic dosing. Total drug recovery (urinary excretion of intact drug plus unabsorbed dose recovered from tear overflow) was 78% on day one and 90% on day ten.

**HUMAN PHARMACOLOGY**

**Systemic Pharmacokinetics**
In systemic pharmacokinetic studies, ofloxacin was rapidly absorbed into the blood stream following oral dosing, with peak serum concentrations \( (C_{\text{max}}) \) increasing in a dose-related manner. There was no significant increase in peak serum ofloxacin concentration following multiple oral administrations. Cumulative urinary recovery of ofloxacin 48 hours after dosing ranged from 83% to 99% of the administered dose. This indicates that ofloxacin is mainly excreted by renal elimination.

**Metabolism Characteristics and Metabolites**
The metabolism of ofloxacin was studied in five healthy adult male volunteers receiving a single oral dose of a 600 mg mixture of ofloxacin and deuterium-labeled ofloxacin. Ofloxacin and its metabolites were identified, confirmed and quantified using thin layer chromatography, UV spectrophotometry, high pressure liquid chromatography, fluorometry and other methods. Urinary concentration of ofloxacin increased to a maximum of 686.6 mcg/mL at 2-4 hours after dosing and was maintained above 273.9 mcg/mL 4-24 hours after dosing.

Cumulative urinary excretion of ofloxacin was 79.5% at 48 hours after dosing. Urinary concentrations of desmethyl ofloxacin were 10.4 and 6.6 mcg/mL at 2-4 and 12-24 hours after dosing, concentrations of ofloxacin N-oxide were 7.8 and 2.7 mcg/mL at 2-4 and 12-24 hours after dosing. Urinary concentrations of these metabolites were less than 2.5% of the excreted concentration of ofloxacin at each time interval.
The results of this study indicate that ofloxacin exists mainly as parent drug \textit{in vivo}, and is excreted mainly unchanged in the urine in humans.

**Drug Interactions**

Interactions between ofloxacin and caffeine have not been detected. Systemic use of ofloxacin with non-steroidal anti-inflammatory drugs has shown that the risk of CNS stimulation and convulsive seizures may increase. A pharmacokinetic study in 15 healthy males has shown that the steady-state peak theophylline concentration increased by an average of approximately 9\% and the AUC increased by an average of approximately 13\% when oral ofloxacin and theophylline were administered concurrently.

**TOXICOLOGY**

**ANIMAL TOXICITY STUDIES**

**Acute Systemic Toxicity**
The acute LD$_{50}$ values of ofloxacin were evaluated in several animal species by oral, subcutaneous or intravenous administration. The LD$_{50}$ values for each study are listed in Table 3.

Most frequently observed signs in the acute toxicity studies included: vomiting, decreased motor activity, respiratory depression, prostration, convulsions, collapse, and respiratory arrest.

**Subacute/Chronic Systemic Toxicity Studies**

Ofloxacin was administered in repeated doses in rats, dogs and monkeys for periods of up to 52 weeks. The most notable effect seen in these studies was the effect of ofloxacin on articular cartilage in immature animals. Several special studies of the effects of ofloxacin on articular cartilage were conducted. Orally administered ofloxacin had no effect on articular cartilage in
mature rats and dogs. However, in immature animals, daily treatment for 7 days with ofloxacin at 300 mg/kg (but not at 100 mg/kg) in rats and at 10 mg/kg (but not at 5 mg/kg) in dogs produced arthropathic effects.

Studies were conducted to elucidate the mechanism of action, onset, recovery and effects of age and dosage on arthropathy associated with ofloxacin and other quinolones. The studies indicate that toxicity to weight-bearing joints is dose-related at oral dosages far higher than topical ophthalmic dosages and that toxic effects are seen only in growing animals. Damage to joints was partially repairable, although some damage appeared to be permanent. Damage such as erosion of the cartilage occurs in weight-bearing joints where "bubbles" (inconsistencies in growth) have developed in the cartilage.

Other findings from subacute and chronic studies are listed in Table 4.

Note: Ofloxacin was administered in a 0.5% carboxymethylcellulose suspension in rats. In dogs and monkeys, it was administered in gelatin capsules.
Carcinogenic Potential
Because ophthalmic ofloxacin solution is not intended for chronic use, specific carcinogenicity studies were not carried out. Chronic ophthalmic toxicity studies showed no evidence of carcinogenic potential.

Mutagenicity Potential
Predictive tests included: Ames test, REC-Assay, micronucleus test, sister chromatid exchange in cultured Chinese hamster cells and in human peripheral blood lymphocytes, unscheduled DNA repair synthesis test, dominant lethal assay, and in vitro and in vivo cytogenetic tests.

Extensive tests for mutagenicity showed no mutagenic potential. Mutagenicity tests were conducted with ofloxacin by a number of techniques, both in vitro and in vivo. Dose-related damage to the DNA of Bacillus subtilis was seen in tests using the REC assay technique. The damage to B.subtilis DNA is consistent with the mechanism of action of the drug in bacteria and is not predictive of mutagenic potential in eukaryotic cells. No evidence of significant mutagenic effects was seen in other tests in a variety of eukaryotic somatic or germ cells.

Human blood samples were examined after oral dosing with 200 mg/day of ofloxacin for 1 to 10 weeks (equivalent to 50 times the maximum recommended daily ophthalmic dose). No chromosome-damaging effect was seen in the peripheral blood leukocytes.

Fetal Toxicity and Fertility Studies
The effects of ofloxacin on fertility, reproduction and fetal toxicity were studied in rats and rabbits. The studies are summarized in Table 5. No adverse effects on fertility and general reproductive performance were seen in male or female rats from administration of ofloxacin in dosages of 10 mg/kg/day to 360 mg/kg/day, beginning well before mating and continuing through the seventh day of gestation in females.

Ofloxacin has not been shown to be teratogenic at doses as high as 810 mg/kg/day (equivalent to 13,500 times the maximum recommended daily ophthalmic dose) and 160 mg/kg/day (equivalent to 2600 times the daily ophthalmic dose) when administered to pregnant rats and rabbits, respectively. Additional studies in rats with doses up to 360 mg/kg/day during late gestation showed no adverse effect on late fetal development, labor, delivery, lactation, neonatal viability, or growth of the newborn. Doses of 810 mg/kg/day and 160 mg/kg/day resulted in decreased fetal body weight and increased fetal mortality in rats and rabbits, respectively. Minor fetal skeletal variations were reported in rats receiving doses of 810 mg/kg/day.

SPECIAL TOXICITY STUDIES

Ocular Toxicity
Ocular toxicity studies were conducted in rabbits and monkeys with ofloxacin ophthalmic solutions. Results indicate that ofloxacin ophthalmic solutions are not toxic to the eyes under the conditions tested, including dosing up to 16 times per day. Ocular toxicity studies of up to three months duration are included in Table 6 following this page. Chronic ocular toxicity studies are included in Table 7. No local or systemic toxicity was observed as a result of ocular administration of ofloxacin for up to six months in rabbits or monkeys.

Other Special Toxicity Studies
No evidence of ototoxicity, antigenicity or skin sensitization was seen in guinea pigs. Studies in rabbits revealed no evidence of nephrotoxicity.

Special Studies of Tissue Distribution and Accumulation
Special studies of tissue distribution and accumulation, with special reference to the eye tissues, were conducted due to the tendency of ofloxacin to bind to the pigment melanin, which is present in some ocular structures. Studies with the topical solution showed definite binding to melanin which decreased slowly after withdrawal of the drug. In vitro studies with bovine melanin showed the affinity of ofloxacin for melanin to be greater than that of timolol and pilocarpine, but less than that of chloroquine and befunolol. The binding was reversible. A four-week study in pigmented rats revealed no evidence of ocular toxicity after daily oral doses of 100 mg/kg/day. Results of this study were consistent with the lack of ocular toxicity seen in multi-dose ocular and systemic toxicity studies in dogs and monkeys.

Studies conducted specifically to study melanin binding are included in Table 8. Table 9 contains the half-life estimates for ofloxacin in the aqueous humor and lens after oral dosing and the concentrations of ofloxacin found in various ocular tissues after topical dosing.

PART III: CONSUMER INFORMATION

Sandoz Ofloxacin
Ofloxacin Ophthalmic Solution USP, 0.3%

This leaflet is part III of a three-part "Product Monograph" published when Sandoz Ofloxacin was approved for sale in Canada and is designed specifically for Consumers. This leaflet is a summary and will not tell you everything about Sandoz Ofloxacin. Contact your doctor or pharmacist if you have any questions about the drug.

ABOUT THIS MEDICATION

What the medication is used for:
Sandoz Ofloxacin is a topical treatment for external eye infections such as conjunctivitis.

Antibacterial drugs like Sandoz Ofloxacin treat only bacterial infections. They do not treat viral infections. Although you may feel better early in the treatment, Sandoz Ofloxacin should be used exactly as directed. Misuse or overuse of Sandoz Ofloxacin could lead to the growth of bacteria that will not be killed by Sandoz Ofloxacin (resistance). This means that Sandoz Ofloxacin may not work for you in the future. Do not share your medicine.

What it does:
Sandoz Ofloxacin interferes with the bacterial enzyme responsible for growth and division, thereby helping stop the infection.

When it should not be used:
Do not use Sandoz Ofloxacin if you:

- Have a history of hypersensitivity to ofloxacin or to any of the ingredients of this medication (See What the important nonmedicinal ingredients are).
- Have a history of hypersensitivity to other quinolones.

What the medicinal ingredient is:
Sandoz Ofloxacin contains the antibiotic, ofloxacin, which is a member of the group of antibiotics known as “quinolones”.

What the important nonmedicinal ingredients are:
Benzalkonium chloride 0.005% w/v (as preservative), sodium chloride, hydrochloric acid and/or sodium hydroxide to adjust the pH, and purified water.

What dosage forms it comes in:
Sandoz Ofloxacin is supplied in plastic Drop-Tainer® dropper bottles containing 5 mL.

WARNINGS AND PRECAUTIONS

This product should be used with caution in patients with a defect or damage to the surface of the eye.

Your sight may become blurred for a short time just after using Sandoz Ofloxacin. You should not drive or use machines until your sight is clear again.

BEFORE you use Sandoz Ofloxacin talk to your doctor or pharmacist if:
- You are pregnant or intend to become pregnant.
- You are breastfeeding or planning to breastfeed
- You have any allergies to this drug, or to similar drugs (ask your doctor) or to Sandoz Ofloxacin’s ingredients or components of its container
- You wear contact lenses. The preservative in Sandoz Ofloxacin (benzalkonium chloride) may be absorbed by and discolour softcontact lenses. Lenses should be removed prior to application of Sandoz Ofloxacin and kept out for 15 minutes after use.

INTERACTIONS WITH THIS MEDICATION

Drug interaction studies have not been done for Sandoz Ofloxacin.

Tell your doctor or pharmacist if you are taking any other prescription or nonprescription (over-the-counter [OTC]) medicine, vitamins, herblals products.

PROPER USE OF THIS MEDICATION

Usual adult dose:
One to two drops every two to four hours for the first two days, and then four times daily in the affected eye(s) for 8 days.

How to Use:
1. Wash your hands. Tilt your head back and look at the ceiling.

2. Gently pull the lower eyelid down until there is a small pocket.

3. Turn the bottle upside down and squeeze it to release one or two drops into each eye that needs treatment.

Sandoz Ofloxacin
3. 

4. Let go of the lower lid, and close your eye for 30 seconds.

If a drop misses your eye, try again.
To avoid contamination and injury, do not let the tip of the dropper touch your eye or anything else.
Replace and tighten the cap straight after use.
The proper application of your eye drops is very important. If you have any questions ask your doctor or pharmacist.

**Overdose:**

If you have placed too many drops in your eye(s), wash the eye(s) with clean water. Apply your next dose at the normal time.

In case of drug overdose, contact a health care practitioner, hospital emergency department or regional Poison Control Centre immediately, even if there are no symptoms.

**Missed Dose:**

If you forget to apply your eye drops at your normal time, simply apply them as soon as you remember. Then go back to the original schedule as directed by your doctor. **Don’t try to catch up on missed drops by applying more than one dose at a time.**

**SIDE EFFECTS AND WHAT TO DO ABOUT THEM**

You should see your doctor if any of the following side effects that affect the eye(s) prove troublesome or if they are long lasting:

- temporary burning or discomfort
- irritation
- eye/eyelid swelling
- eye pain
- redness
- stinging
- itchy eye/eyelid
- tearing
- dryness
- light sensitivity
- blurred vision
- a feeling that something is in your eye

You should see your doctor if any of the following side effects that affect the body prove troublesome or if they are long lasting:

- dizziness
- nausea
- swelling of the face

Stop Sandoz Ofloxacin use and contact your doctor if a severe allergic (hypersensitivity) reaction occurs with symptoms such as swelling of the mouth, throat, tongue or extremities (hands, feet), difficulty in breathing, skin reactions (redness, irritation, blistering, peeling), loss of consciousness or collapse.

This is not a complete list of side effects. For any unexpected effects while taking Sandoz Ofloxacin contact your doctor or pharmacist.

**HOW TO STORE IT**

Sandoz Ofloxacin should be stored between 4°C to 30°C.

Keep out of reach and sight of children.

**Reporting Side Effects**

You can report any suspected side effects associated with the use of health products to Health Canada by:

- Visiting the Web page on Adverse Reaction Reporting (http://www.hc-sc.gc.ca/dhp-mps/medeff/report-declaration/index-eng.php) for information on how to report online, by mail or by fax; or
- Calling toll-free at 1-866-234-2345.

NOTE: Contact your health professional if you need information about how to manage your side effects. The Canada Vigilance Program does not provide medical advice.
