PRESCRIBING INFORMATION

HEPARIN SODIUM INJECTION USP

1 000 and 10 000 USP Units/mL

Sterile

Anticoagulant

Sandoz Canada Inc.
145 Jules-Léger
Boucherville, QC, Canada
J4B 7K8

Date of Preparation: November 19th, 2007.
Date of Revision: January 25th, 2008
DESCRIPTION

Heparin Sodium Injection USP is a sterile, pyrogen-free solution of a highly purified sodium salt of heparin, a high molecular weight polysaccharide derived from porcine intestinal mucosa. It is standardized in vitro according to the method of the USP and is labelled in terms of USP units for use as an anticoagulant. It acts very rapidly and, even in large doses, is metabolized in the body and eliminated within 24 hours. It will not lyse existing thrombi or emboli.

ACTIONS

Heparin inhibits the clotting of blood and the formation of fibrin clots both in vitro and in vivo. In combination with a cofactor, it inactivates thrombin thus preventing the conversion of fibrinogen to fibrin. Heparin also prevents the formation of a stable fibrin clot by inhibiting the activation of the fibrin stabilizing factor.

Heparin sodium inhibits reactions which lead to clotting but does not alter the normal components of the blood. Although clotting time is prolonged by therapeutic doses, bleeding time is usually unaffected. Heparin sodium does not have fibrinolytic activity; therefore, it will not lyse existing clots.

INDICATIONS AND CLINICAL USE

Used in the treatment of thrombophlebitis, phlebothrombosis, and cerebral, coronary, and retinal vessel thrombosis to prevent extension of clots and thromboembolic phenomena.

Also used prophylactically to prevent the occurrence of thromboembolism, and to prevent clotting during dialysis and surgical procedures, particularly vascular surgery.

When using Heparin Sodium Injection USP in conjunction with dialysis machines or where the Heparin Sodium Injection USP is added to dextrose or saline it is most important that the pH is not less than 5 for Heparin Sodium Injection USP to act as an effective anticoagulant. Under pH 5 degradation sets in and with a pH around 4 or less there is very little Heparin Sodium Injection USP activity. Likewise with pH over 8.5 there will be some degradation. Recent work
has indicated that early hemodialysis is of value in cases of multiple trauma.

Heparin Sodium Injection USP has also been used as an anticoagulant in blood transfusion samples, particularly when the presence of citrates, oxalates or fluorides might interfere with laboratory tests, such as electrolyte determination. Anti-inflammatory and diuretic activity has been obtained with Heparin Sodium Injection USP, however, these properties have not yet been put to any widespread clinical use.

**Low-Dose Subcutaneous Heparin**
For the prevention of serious venous thromboembolic complications in high-risk surgical patients.

**CONTRAINDICATIONS**
Patients with a generalized clotting disorder such as hemophilia, Christmas disease, idiopathic thrombocytopenic purpura and patients with active bleeding from a local lesion such as an acute ulcer or ulcerating carcinoma; patients who have had recent cranial, spinal, eye or ear surgery or trauma; hypersensitivity to heparin, including thrombocytopenia; severe liver damage; shock.

**WARNINGS**
Administration of large doses of Heparin Sodium Injection USP should be delayed four hours postoperatively.

When any of the conditions mentioned under **PRECAUTIONS** are present the advantages of Heparin Sodium Injection USP therapy must be carefully weighed against the possibility of deleterious results.

**PRECAUTIONS**
The use of IV heparin in the treatment of ischemic stroke is controversial. Clinical trials investigating the benefits of heparin in ischemic stroke have been inconclusive. Heparin may increase the risk of clinically significant cerebral bleeding. Administration of an IV bolus of heparin is not recommended in the treatment of stroke. If heparin is used, brain imaging should be performed prior to initiation of therapy to exclude hemorrhage and estimate infarct size.

When considered for use in any of the following conditions, the advantages of heparin therapy must be carefully weighed against the risks: subacute bacterial endocarditis; increased capillary permeability; dissecting aneurysm; severe hypertension; during and immediately following major surgery, especially of the brain, spinal cord, eye or ear; conditions associated with increased bleeding tendencies such as hemophilia,
thrombocytopenia and some purpuras; inaccessible gastrointestinal ulcers; ulcerative colitis; continuous tube drainage of stomach or small intestine; threatened abortion; menstruation; malignant hypertension.

Heparin Sodium Injection USP should be used with caution in the immediate postoperative period. Bleeding may be concealed, as in the case of hemothorax.

In patients with a history of heparin-induced thrombocytopenia (HIT), heparinoids (e.g. danaparoid), lepirudin and ancrod are considered appropriate alternatives to heparin.

When used in therapeutic doses, heparin should be regulated by frequent blood coagulation indicators particularly the APTT. If the indicator is unduly prolonged or if hemorrhage occurs, heparin should be at least temporarily discontinued (see OVERDOSAGE).

Heparin can prolong the prothrombin time.

Apparent resistance to heparin may be encountered in patients with acquired or familial AT III deficiency, because adequate levels of AT III are required for heparin’s anticoagulant effect. Larger doses of heparin may be required initially in patients with various disease states due to alterations in their physiology, the pharmacokinetics of the drug, or elevations in levels of acute phase heparin-binding proteins. Among these are febrile illness, infections associated with thrombosing tendencies, pulmonary embolism, myocardial infarction, extensive thrombotic disorders especially those associated with neoplastic disease and following surgery.

Heparin should be used with caution in the presence of severe hepatic or renal disease, or in patients with indwelling catheters. A higher incidence of bleeding may be seen in women over 60 years of age.

IM injections of other drugs should be avoided during heparin therapy to reduce the risk of hematoma formation and bleeding from the site. Most drugs can be given by another route (IV or SC).

For these reasons, strict laboratory control of dosage is necessary. Heparin Sodium Injection USP should be used with caution in patients with allergy. Patients on long-term daily administration of Heparin Sodium Injection USP should be observed for the possible development of osteoporosis and spontaneous fractures of ribs and/or vertebrae.

**Drug Interactions**
Oral anticoagulants (i.e. warfarin) can contribute to a small extent to an increase in APTT. Heparin can contribute to an increase in PT. While these two drugs are given together, the fact that each may contribute to an increase in PT and APTT should be taken into account (see PRECAUTIONS).
Heparin is often started with or several hours after thrombolytic therapy. Close patient monitoring for clinical signs of bleeding is indicated. The APTT should also be monitored closely (see **DOSAGE AND ADMINISTRATION**).

Salicylates, other nonsteroidal anti-inflammatory agents, dextran, dipyridamole, clopidogrel, ticlopidine and GPIIb-IIIa antagonists (e.g. abciximab) interfere with platelet aggregation which increases the risk of bleeding. They should be used cautiously with monitoring for signs of hemorrhage. In addition, in some situations, when heparin is used in conjunction with GPIIb-IIIa antagonists, the dose of heparin may need to be modified (see **DOSAGE AND ADMINISTRATION, THERAPY REQUIRED, Coronary and Vascular Surgery**).

Cefamandole, cefotetan, methimazole, propylthiouracil and valproic acid may cause hypoprothrombinemia and increase the risk of bleeding; monitoring for signs of bleeding is indicated. This may occur to a lesser extent with cefazolin, cefoxitin and ceftriaxone.

IV nitroglycerin may reduce heparin’s anticoagulant effect and necessitate higher doses. This interaction has been reported to occur regardless of whether or not propylene glycol is used as a solvent for the nitroglycerin.

The mechanism has not been conclusively documented. When IV nitroglycerin therapy is initiated, patients should be closely monitored to ensure anticoagulation remains adequate. Likewise, when nitroglycerin therapy is stopped, a decrease in heparin dosage may be necessary and patients should be monitored for signs of excessive anticoagulation.

Digitalis, quinine, ACTH, insulin, corticosteroids, antihistamines and nicotine have been reported to interfere with the anticoagulant effect of heparin; however, there is no substantial literature support to document these interactions.

Care must be taken where large doses of antibiotics and/or drugs containing amino groups are administered along with or prior to Heparin Sodium Injection USP administration. Drugs such as codeine phosphate, pethidine hydrochloride, streptomycin, erythromycin, kanamycin, neomycin, novobiocin, tetracyclines, ampicillin, penicillin G, polymyxin B, vancomycin, hydrocortisone sodium succinate (S-Cortilean), pentobarbital, promazine hydrochloride, vitamin B complex, vitamin C.

Heparin Sodium Injection USP may complex with these drugs – this complex may be reversible (heparin rebound) and may result in excess bleeding at the surgical site. Extra protamine sulfate may then be indicated.

Please also refer to the pH requirements in hemodialysis under **INDICATIONS**.
**Incompatibilities**

Although digitalis, quinine, tetracycline, antihistamines, and nicotine have been stated to interfere with the anticoagulant activity of heparin, there is no substantial literature support for such interactions. The chemical interaction occurring between heparin and protamine is well known. This interaction is used clinically to antagonize the anticoagulant effect of heparin.

**Ethacrynic Acid:** Intravenously administered ethacrynic acid can cause GI bleeding. However, a significantly higher incidence of GI bleeding has been attributed to the concurrent use of intravenous ethacrynic acid and heparin. Furosemide may be a safer alternative when such diuretic therapy is indicated in the patient receiving heparin.

**Acetylsalicylic Acid:** In a review article of heparin therapy, it was advocated that concurrent acetylsalicylic acid administration be scrupulously avoided. While documentation to support this interaction is incomplete, it would be prudent to avoid concurrent therapy. Acetylsalicylic acid impairs the platelet release reaction and this platelet function defect combined with the anticoagulant effect of heparin may produce a hemorrhagic tendency.

**Dextran:** Limited data suggest that dextran and heparin may act synergistically when administered concurrently. Although the data are inadequate to document the clinical significance of this interaction, baseline laboratory measurements of anticoagulant activity should be obtained upon initiation of concurrent therapy as well as at frequent intervals during such therapy.

**Pregnancy**

Heparin does not cross the placenta and has not been related to congenital defects. However, its use during pregnancy has been associated with a 13 to 22% risk of fetal mortality or prematurity. It is not clear whether severity of maternal disease or an indirect effect of heparin is responsible. Coumarin anticoagulants have been associated with a 31% incidence of unfavourable outcome and a definite drug-induced pattern of malformations has been demonstrated (fetal warfarin syndrome). However, the incidence of warfarin-induced fetopathic effects in the second and third trimesters is very low. In general, heparin is considered to be the anticoagulant of choice in pregnancy. Long-term usage (>3 to 5 months) of therapeutic doses of heparin during pregnancy increases the risk of osteoporosis and warrants careful monitoring of patients. Heparin therapy during the last trimester and immediate postpartum period is associated with a risk of maternal hemorrhage.

Changes in pharmacokinetics during pregnancy require caution and close patient monitoring if heparin is used. Reports of therapeutic failure with adjusted-dose heparin therapy in pregnant patients with prosthetic heart valves may have been due to inadequate dosing and/or monitoring or to an inherent lack of efficacy in these patients. The American College of Chest Physicians recommends that if subcutaneous heparin is used in pregnant patients with mechanical heart valves, it be administered every 12 hours and the dose adjusted to keep the mid-interval APTT at least twice the control, or an anti-Xa heparin level of 0.35 to 0.7 U/mL. In addition, some clinicians suggest an initial dose of 17 500 to 20 000 units SC every 12 hours.
Lactation
Heparin is not excreted in breast milk because of its high molecular weight.

ADVERSE REACTIONS

Bone and Joint: Therapeutic doses of heparin administered for longer than 3 months have been associated with osteoporosis and spontaneous vertebral fractures.

Recent reports indicate that osteoporosis may be reversible after discontinuation of heparin.

Hematologic: Bleeding is the most common side effect of heparin and is an extension of its pharmacological effect. The rate of occurrence is approximately 10% overall but may increase up to 20% in patients treated with high-dose therapy. Risk of bleeding likely increases with APTT ratios above the recommended target range. Other risk factors associated with bleeding are: a serious concurrent illness, chronic heavy consumption of alcohol, use of platelet-inhibiting drugs, renal failure, age and female sex. Bleeding may range from minor local ecchymoses to major hemorrhagic events. Often the first sign of bleeding may be epistaxis, hematuria or melena. Bleeding may be from any site and can be difficult to detect, e.g. retroperitoneal bleeds. Bleeding may also occur from surgical sites. Petechiae or easy bruising may precede frank hemorrhage. A supratherapeutic APTT or minor bleeding during therapy can usually be controlled by adjusting the dosage or withdrawing the drug (see OVERDOSAGE).

Thrombocytopenia has also been described with heparin treatment. Heparin-induced thrombocytopenia (HIT) is an allergic reaction. It has been reported to occur in 1 to 30% of patients treated with standard heparin. It has also occurred with the use of LMWHs, both in patients with a history of HIT and patients with no previous exposure to heparin. The risk of developing HIT may be lower with LMWHs, but cannot be reliably estimated until more patients have been exposed. It is thought to be more common with heparin derived from bovine lung (5-10%) than from porcine gut (2-5%). Two types of acute, reversible thrombocytopenia have been described. Mild thrombocytopenia most commonly occurs between 5 and 12 days after initiation of full dose therapy. Platelet count usually remains above 100 x 10^9/L, and heparin therapy does not necessarily have to be withdrawn. Platelet count may remain stable or even increase despite continued therapy; however, it should still be monitored. The more severe, delayed form of thrombocytopenia (platelet <100 x 10^9/L), is much less frequent, usually appearing 5 to 12 days after starting heparin therapy and recurs rapidly on rechallenge. It has occurred with low dosages and is not dose related. It is generally reversible, platelet counts usually begin to return to normal within 4 days of stopping heparin. Paradoxically, patients may develop thrombotic complications including arterial thrombosis, gangrene, stroke, myocardial infarction and disseminated intravascular coagulation. Thrombosis is due to white clots composed of platelets and fibrin that result from marked in vivo platelet aggregation. Patients receiving heparin acutely should have platelet counts monitored at least every 2 or 3 days.
**Hepatic:** Heparin has been reported to cause elevations of AST and ALT in approximately 27 and 59% of patients, respectively. Transient increases in serum LDH levels have also occurred. No clinical signs of liver dysfunction have been reported and the significance is not known, except that interpretation of liver enzymes for other purposes (i.e. liver disease) must take into consideration the possible contribution of heparin.

**Hypersensitivity:** Heparin-induced thrombocytopenia (see ADVERSE EFFECTS, Hematologic). Other allergic reactions to heparin are rare. The most common manifestations of hypersensitivity are chills, fever and urticaria. Asthma, rhinitis, tearing, headache, nausea, vomiting, shock and anaphylactoid reactions have also occurred. Vasospasm has been reported 6 to 10 days after starting heparin; the etiology is thought to be allergic. Vasospasm often appears in a limb where an artery has recently been catheterized. The affected limb is usually painful, ischemic and cyanotic. Protamine sulfate is of no use in hypersensitivity reactions.

**Miscellaneous:** Alopecia, affecting the entire scalp or confined to the temple, may occur. Itching and burning of the plantar surfaces of the feet, suppression of aldosterone product, hyperkalemia (due to aldosterone suppression), priapism and rebound hyperlipidemia have also been reported.

**Heparin Neutralization with Protamine**

Bleeding which may occur during therapy with heparin can usually be corrected by withdrawal. Clotting time should then return to normal in 30 to 60 minutes provided venous clotting time is not longer than 15 minutes when the infusion is interrupted. Should withdrawal of heparin sodium fail to control bleeding, fresh, matched blood (not more than three days old) may be administered in quantities of 250 to 500 mL.

The most rapid means of counteracting the effects of heparin is intravenous administration of protamine sulfate injection. However, protamine is by itself an anticoagulant and therefore excess must be avoided. **A dosing ratio of 1 mg of protamine for every 100 units of heparin remaining in the patient is the usual rule.** It is recommended that protamine doses be guided by blood coagulation studies to determine if additional doses are required. The activated partial thromboplastin time (APTT) or activated clotting time (ACT) are adequate for this purpose.

Allowance should be made for the rapid removal of heparin from circulation. The rate of heparin removal from plasma is dose-dependent. However, it may be assumed that about 30 minutes after an intravenous injection, about 50% of the heparin is removed from circulation.

So the amount of protamine sulfate required to neutralize the heparin will be approximately half of that required for the original dose. For example, if 1 000 units required 8.4 mg of protamine sulfate for neutralization, half an hour after intravenous administration of a 5 000 unit dose, the amount of protamine sulfate required will only be approximately

\[
\frac{5}{2} \times 8.4 = 21 \text{ mg}
\]
Too rapid administration of protamine can cause severe hypotensive and anaphylactoid reactions. Facilities to treat shock should be readily available when administering protamine. The rate of protamine administration should not exceed 20 mg/min and no more than 50 mg should be given in any 10-minute period. Doses exceeding 100 mg in a short period of time should be avoided, unless there is certain knowledge of larger protamine requirements. Any excess protamine sulfate, not complexed to heparin, has its own intrinsic anticoagulant effect. However, one study found overdose of protamine up to 600 to 800 mg IV to have only minor, transient effects on blood coagulation.

OVERDOSE

Symptoms: Overdose may be manifested by excessive prolongation of the APTT or by bleeding. Bleeding may be internal or external, major or minor.

Treatment: See ADVERSE EFFECTS, Heparin Neutralization with Protamine.

DOSAGE AND ADMINISTRATION

Please Note:

- Intramuscular injection (especially in the arm or thigh) and shallow subcutaneous injection is not recommended. The duration of effect is shortened and it is more likely to produce pain and hematoma.

- Heparin sodium activity is expressed in USP units and should be prescribed in units only.

The route of administration may be IV or SC depending upon the situation and the choice of the prescriber. Adequate heparin-induced anticoagulant therapy is present when the clotting time is elevated from 2 to 3 times normal as measured by the Lee-White method. Two types of dosage schedules are suggested: Heparin Sodium Injection USP may be administered intravenously in a dose of 5 000 USP units every 4 hours or in a dose of 10 000 USP units every 6 hours, depending upon the results of a whole blood clotting time test performed at the bedside just prior to each additional dose. If the clotting time is less than twice normal, the next dose is increased by one-third to one-half. If the clotting time is more than 2½ times normal, the next dose is decreased by one-third to one-half. If the clotting time is between 2 and 2½ times normal, the regular dose is repeated.
Subcutaneous Injection Technique
Use of a 1 mL tuberculin syringe with a N° 25 or N° 26 ½ inch needle is recommended.

Step 1: Disinfect area with alcohol than apply pressure between finger and thumb to the dermal fold until the injection site is blanched.

Step 2: Insert the needle into the raised, blanched area. Reduce the pressure on the skin and inject the Heparin Sodium Injection USP slowly.

Step 3: Withdraw the needle quickly and apply alcohol swab with pressure to the site of injection for 5-10 seconds to prevent loss of the heparin.

*Based on 68 kg of body weight (approx. 150 lbs)
† It is not necessary to monitor low-dose prophylactic Heparin Sodium Injection USP.
**Following immediately after an initial dose of 5 000 units IV.

Dilution Instructions for IV Infusion
Heparin Sodium Injection USP may be diluted between the concentration range of 20 to 100 IU/mL with the diluents Sodium Chloride Injection USP 0.9% (qs. 100 mL) and/or Dextrose Injection USP 5% (qs. 100 mL). Diluted solutions can be stored up to 24 hours between 20 and 30°C and exposed to light. Diluted solution should be verified for particulate matter prior to administration.

As with all parenteral drug products, intravenous admixtures should be inspected visually for clarity, particulate matter, precipitate, discolouration and leakage prior to administration, whenever solution and container permit. Solutions showing haziness, particulate matter, precipitate, discolouration or leakage should not be used. Discard unused portion.
Therapy Required

1. **Low-Dose Subcutaneous Heparin**
   There is now good evidence that low-dose heparin is effective in preventing serious venous thromboembolic complications in high-risk surgical patients. The usually recommended dose is 5 000 units given subcutaneously 2 hours before surgery and then 5 000 units given either every 12 hours or every 8 hours after surgery with the first dose given at approximately 12 hours after surgery. It is not necessary to monitor low-dose prophylactic heparin.

2. **Therapeutic Anticoagulant Action (Immediate and Short Term)**
   The dose should be adjusted in keeping with the patient’s clotting time which should be determined just prior to the injection during the first day of treatment. It is also recommended that, in order to help regulate dosage, the clotting time be determined on the second and third day of treatment. (The recommended method is the Lee-White whole blood method).

   Anticoagulation is adequate when the clotting time is 2 to 3 times the normal value.

   Subcutaneous administration is usually employed for maintenance therapy after initial regulation.

3. **Long-Term Protective Anticoagulant Action**
   Subcutaneous administration of 15 000 units every 12 hours is usually employed. Daily injections of 20 000 to 30 000 units have also been employed with success. After initial regulation the dosage should be adjusted according to weekly to monthly clotting time determinations. Anticoagulant therapy should not be terminated abruptly but should be gradually reduced over 3-4 days.

4. **Deep Venous Thrombosis and Pulmonary Embolism**
   Dosage of 20 000 units daily for 6 to 10 days has been of value.

5. **Hemodialysis**
   **Multiple Trauma:**
   Recent literature has suggested the use of early hemodialysis in multiple trauma.

   **Chronic Renal Failure:**
   The use of hemodialysis in this area has increased dramatically in recent years and may be in-hospital or home dialysis.

   It is most important to stress that the instructions for each manufacturer’s equipment unit must be followed scrupulously.

   The following is merely intended as an overall summary of possible general procedures:

   - 3 000 units of Heparin Sodium Injection USP is added to 1 000 mL of sterile
saline as dialyser flush prior to connection.

- **Initial Dosage**: 5 000 units of Heparin Sodium Injection USP into the venous shunt or 2 500 units into the arterial fistula needle.

- With the shunt type the usual continuing dosage is 2 000 units per hour; with the fistula type, 1 500 units per hour by means of suitable syringe and a pump to allow continuing infusion. Heparin Sodium Injection USP reversal with protamine sulfate will be decided by the individual physician. Usually this is not done unless dialysis is being performed soon after surgery.

6. **Coronary and Vascular Surgery**
Patients undergoing total body perfusion for open-heart surgery should receive an initial dose of not less than 150 units of Heparin Sodium Injection USP per kilogram of body weight. Frequently a dose of 300 units of Heparin Sodium Injection USP per kilogram of body weight is used for procedures estimated to last less than 60 minutes; or 400 units/kg for those estimated to last longer than 60 minutes.

**PHARMACEUTICAL INFORMATION**

**Drug Substance**

**Proper Name**: Heparin Sodium

**CAS No.**: 9041-08-1
Description: Heparin is a heterogeneous group of straight-chain anionic mucopolysaccarides, called glycosaminoglycans, having anticoagulant properties. Although others may be present, the main sugars occurring in heparin are: (1) α-L-iduronic acid 2-sulfate, (2) 2-deoxy-2-sulfamino-α-D-glucose 6-sulfate, (3) β-D-glucuronic acid, (4) 2-acetamido-2-deoxy-α-D-glucose, (5) α-L-iduronic acid. These sugars are present in decreasing amounts, usually in the order (2) > (1) > (4) > (3) > (5), and are joined by glycosidic linkages, forming polymers of varying sizes. Heparin is strongly acidic because of its content of covalently linked sulfate and carboxylic acid groups. In heparin sodium, the acidic protons of the sulfate units are partially replaced by sodium ions. Heparin sodium is derived from porcine intestinal mucosa, standardized for anticoagulant activity.

Stability and Storage Recommendations: Store Heparin Sodium Injection USP vials between 15 and 30°C. Protect from light. Protect from freezing. For single use vials, discard unused portion. For multidose vials, discard unused portion 28 days after initial puncture.

AVAILABILITY

Each mL of Heparin Sodium Injection USP 1 000 USP Units/mL (multidose) contains heparin sodium 1 000 USP Units/mL, benzyl alcohol 10 mg, sodium chloride 5.8 mg, sodium hydroxide and/or hydrochloric acid to adjust the pH, water for injection. Heparin Sodium Injection USP 1 000 USP Units/mL (multidose) is available in boxes of 10 vials, in 10 mL and 30 mL format.

Each mL of Heparin Sodium Injection USP 10 000 USP Units/mL (multidose) contains heparin sodium 10 000 USP Units/mL, benzyl alcohol 10 mg, sodium chloride 2.2 mg, sodium hydroxide and/or hydrochloric acid to adjust the pH, water for injection. Heparin Sodium Injection USP 10 000 USP Units/mL (multidose) is available in boxes of 10 vials in 5 mL format and in a box of 1 vial in a 50 mL multiple dispensing single puncture pharmacy bulk format.

Each mL of Heparin Sodium Injection USP 10 000 USP Units/mL preservative free (single use) contains heparin sodium 10 000 USP Units/mL, sodium chloride 5.0 mg, sodium hydroxide and/or hydrochloric acid to adjust the pH, water for injection. Heparin Sodium Injection USP 10 000 USP Units/mL (single use) is available in boxes of 10 vials in a 1 mL format.

LATEX-FREE STOPPER: Stopper contains no dry natural rubber.
